PROTOCOL

. Digitally Enhanced Recovery: Investigating the Use of Digital Self-Tracking for Monitoring Leisure Time Physical Activity of Cardiovascular Disease (CVD) Patients Undergoing Cardiac Rehabilitation

CONTACT: [Jürgen Vogel](#)

SAFETY INFORMATION

sdffds

Method

Step 5.1.

Select male patients who attend outpatient cardiac rehabilitation phase II (follow-up treatment after early mobilization or hospital stay after an acute cardiac event) randomly and divide them into two groups by a standard software-based random sample generator.

Method

Step 5.2.

Provide one group of patients, referred to as 'study group', with activity trackers for a duration of 12 weeks and ask them to perform a supplementary examination at the end of their observation period. Ask the other group of patients, referred to as 'control group', to undergo a supplementary examination 12 weeks after commencement of their rehabilitation without any further intervention (no activity tracking).

Method

Step 5.3.

To compare improvement of different parameters (e.g., performance of cardiovascular system) between the study and control group, analyze results based on three different examinations (t_1 , t_2 , t_3). Perform the baseline examination at the beginning (in week 1= t_1) and the midterm examination at the end (in week 6= t_2) of the rehabilitation programme. Perform a supplementary examination after 12 weeks (in week 13= t_3). Therefore, the observation period (period for tracking and monitoring of physical activity) is 12 weeks per participant.

Participants

Step 5.4.

Define exclusion criteria: e.g., patients are suffering from Parkinson's disease or other medical conditions such as uncontrolled atrial or ventricular dysrhythmias, or they were unable to participate in MVPA due to physical limitations.

Exclude all participants who are unable to complete rehabilitation for medical reasons.

Participants

Step 5.5.

Define inclusion criteria like age (e.g., 40-80), diagnosis of CVD (e.g., ST-elevation myocardial infarction (STEMI), non-ST-elevation myocardial infarction (NSTEMI), percutaneous coronary intervention (PCI) or coronary revascularisation) within the previous 3 months, physical condition (e.g., clinically stable for at least two weeks before the start of the study), ability to participate in the rehabilitation programme (e.g., follow recommendations about physical activity), ability to give informed consent and having a personal computer with access to the Internet at home.

Participants

Step 5.6.

Give detailed information in the form of an introductory face-to-face conversation (duration approximately 30 minutes) to all participants. The conversation should be about the purpose and procedure of the study, benefits and risks to the participants, effects on medication and lifestyle, expected symptoms, side effects or injuries, information about premature termination of participation, use of data and results, costs of participation, reimbursement of costs and remuneration, and contact details for further inquiries.

Additionally, give information to all participants in written form in easily understandable language.

Method

Step 5.7.

All participants should attend routine cardiac rehabilitation during the first six weeks of the study with heart rate controlled moderate to vigorous physical activity, nutritional education, and psychological support. Exercises are partly supervised at the rehabilitation centre and partly conducted at home. The recommendation and duration of the patients' medication should not be affected by this field experiment and therefore remain unchanged. Further, there is no additional

medication for reasons related to this study. After the examination six weeks from start participants get medical recommendations for their future lifestyle (including physical activity). For the following six weeks (until the supplementary examination in week 13) the study group participants continue to wear the activity tracker. Thus, for participants in the control group, as in their first six weeks, there is no intervention until the supplementary examination.

Examinations

Step 5.8.

Perform an examination of the participants' physiological performance at the beginning (t_1), in week 6 (t_2), and after 12 weeks (t_3).

Therefore, conduct a graded exercise test (cardiac stress test) on an electronically braked cycle ergometer or treadmill. The exercise test enables the determination of a participant's maximum exercise capacity.

Examinations

Step 5.9.

Use individual ramp protocols according to the latest national guidelines and international recommendations. To ensure comparability of measures of t_1 , t_2 and t_3 , these should be kept identical for all participants during the different examinations.

Examinations

Step 5.10.

Monitor heart rate continuously by a conventional 12 lead ECG with ten electrodes.

Examinations

Step 5.11.

Measure blood pressure manually with a standard medical measuring device.

Examinations

Step 5.12.

Let participants perform maximum capacity exercise testing until exhaustion or until individual ECG termination criteria were reached. Choose testing protocols lasting 8-12 minutes to the peak of exercise depending on the participant's physical status and capacity. For the test, after an initial warm-up phase with unloaded pedalling, the work rate during progressive uninterrupted exercise should be regularly increased after an adequate time interval in each level until the participant's maximum work rate (power given in W) is reached.

Examinations

Step 5.13.

For comparison of the participants' physiological performance between examination t_1 , t_2 and t_3 and between the study and the control groups use values like the maximum power given in W

achieved by the participants during the cardiac stress test and their calculated relative performance as a percentage (representing their actual performance during the cardiac stress test in relation to their individual target values).

Monitoring PA

Step 5.14.

The tracking and monitoring of study group participants' leisure time physical activity should be performed by using a common consumer smart wearable device (e.g., a bracelet-shaped, wrist-worn 3D accelerometer) with a storage capacity of at least 7 days. The device should allow for easy navigation via the display. Technical support should be ensured in advance by the national representative of the manufacturing company.

Monitoring PA

Step 5.15.

Distribute activity trackers to participants on the day of t_1 and ask them to return them on the day of t_3 .

Monitoring PA

Step 5.16.

Ask participants to wear the device on their non-dominant wrist, if possible, 24 hours a day and seven days a week, to regularly charge the (rechargeable) battery via computer (USB) or charging unit, and to regularly synchronize the automatically collected activity data by using a provided software.

Monitoring PA

Step 5.17.

Provide important information about display views, features and functions, memory capacity, charging and operating time, communication and technical specifications of the device, as well as system requirements for the software and web service, to the participants during the introductory conversation.

Monitoring PA

Step 5.18.

To ensure that the device is comfortable to wear, individually customise the bracelet size to the wrist size of all participants. Give a copy of the user manual to all participants.

Monitoring PA

Step 5.19.

Because of the limited storage capacity of the device, data needs to be synchronised with a computer about once a week to enable ongoing tracking. Data is automatically generated by participants while wearing the activity tracker. For synchronizing data with a computer, ask participants to download and install the synchronising software on their own PC or laptop. As some

of the elderly people were not quite familiar with this kind of process, it should be explained to them in detail. Additionally, provide a copy of an installation guide with step-by-step instructions (including screenshots). If needed prepare user accounts for all participants in advance. Set up activity trackers, update them to the latest software version, and connected them to the accounts.

Monitoring PA

Step 5.20.

Set privacy preferences of the web service to the most private level. Give personal login data to access the pre-set accounts to participants immediately after they had agreed to participate in the study.

Monitoring PA

Step 5.21.

If possible connect participants accounts to a special coaching account held by the study authors. This enables the authors to precisely monitor all synchronised activity data of participants. Inform participants that only the authors and medical staff have access to their activity data and that all personal information such as full name and date of birth is subject to medical confidentiality. For statistical purposes and analysis all data must be anonymised to a study reference number so that it could not be traced to an individual based on published results of the study.

Monitoring PA

Step 5.22.

Advise participants to try to raise their awareness about their own physical activity behaviour, to set realistic and achievable personal goals (such as total daily steps, less overall time spent sitting, or just being more active than the day before).

Monitoring PA

Step 5.23.

Check every three days whether participants were synchronising their activity data regularly. If anyone's data is missing for more than five days, participants should be contacted (personally, by phone, or per e-mail), receive a reminder to synchronise data, or should be asked whether there were any problems (e.g., with synchronisation or use of the device).
