Stranded Transcript Count Table Generation from Long Reads V.8

Forked from Transcript Coverage Analysis from Long Reads

David Eccles¹

¹Malaghan Institute of Medical Research (NZ)

In Development dx.doi.org/10.17504/protocols.io.594g98w

ABSTRACT

This protocol is for comparing different samples at the transcript level, using long reads that are mapped to transcripts.

Input(s): demultiplexed and oriented fastq files (see protocol Preparing Reads for Stranded Mapping), transcript reference fasta file, annotation file

Output(s): transcript table, sorted by differential coverage, annotated with gene name / description / location

BEFORE STARTING

Obtain a transcript fasta file, and an annotation file. For the mouse genome, I use the following files:

- 1. Transcript [CDS] sequences from Ensembl; this file was the most current when I last checked.
- 2. Annotation file obtained from Ensembl BioMart (Ensembl Genes -> Mouse Genes) as a compressed TSV file with the following attribute columns:
- Transcript stable ID
- Gene description
- Gene start (bp)
- Gene end (bp)
- Strand
- Gene name
- Chromosome/scaffold name

Demultiplex Reads

1

Demultiplex and orient reads as per the protocol Preparing Reads for Stranded Mapping. It is expected that these demultiplexed reads will be split up in the current directory, and coupled with a 'barcode_counts.txt' file. If that's the case, the following should work:

```
for bc in $(awk '{print $2}' barcode counts.txt);
 do ls oriented/${bc} reads dirAdjusted.fq.gz;
done
```

Example expected output:

```
oriented/BC03_reads_dirAdjusted.fastq.gz
oriented/BCO4 reads dirAdjusted.fastq.gz
oriented/BC05_reads_dirAdjusted.fastq.gz
oriented/BC06_reads_dirAdjusted.fastq.gz
oriented/BC07_reads_dirAdjusted.fastq.gz
oriented/BC08 reads dirAdjusted.fastq.gz
```

If the 'barcode_counts.txt' file is not present, this error will appear:

```
awk: fatal: cannot open file `barcode_counts.txt' for reading (No such file or directory)
```

If one or more of the oriented read files is missing, it will look something like this:

```
oriented/BC03_reads_dirAdjusted.fastq.gz
oriented/BC04_reads_dirAdjusted.fastq.gz
ls: cannot access 'oriented/BC05_reads_dirAdjusted.fastq.gz':
  No such file or directory
ls: cannot access 'oriented/BC06_reads_dirAdjusted.fastq.gz':
  No such file or directory
oriented/BC07_reads_dirAdjusted.fastq.gz
oriented/BC08_reads_dirAdjusted.fastq.gz
```

Index Preparation

2 Prepare transcript index (see Guidelines for data sources)

```
lastdb Mus_musculus.GRCm38.cds.all.fa <(zcat Mus_musculus.GRCm38.cds.all.fa.gz)
```

Transcriptome Mapping

3 Reads are mapped to the transcriptome with LAST.

The results of that mapping can be piped through *last-map-probs* to exclude unlikely hits, then through *'maf-convert -n tab'* to convert to a one-line-per-mapping CSV format. This CSV format is further processed to make sure that there is only one mapping per transcript-read pair.

```
mkdir -p mapped
for bc in $(awk '{print $2}' barcode_counts.txt);
  do echo "** ${bc} **";
  lastal -Q 1 -P 10 Mus_musculus.GRCm38.cds.all.fa <(pv oriented/${bc}_reads_dirAdjusted.fq.gz |
zcat) | \
    last-map-probs | maf-convert -n tab | cut -f 2,7,10 | sort | uniq | \
    awk -F'\t' -v "bc=${bc}" '{print bc,$1,$3}' | sort | uniq -c | \
    gzip > mapped/trnMapping_LAST_${bc}_vs_Mmus_transcriptome.txt.gz;
done
```

⚠ The result is then aggregated to sum up counts per transcript:

```
for bc in $(awk '{print $2}' barcode_counts.txt);
  do echo "** ${bc} **";
  zcat mapped/trnMapping_LAST_${bc}_vs_Mmus_transcriptome.txt.gz | \
    awk -F'\t' -v "bc=${bc}" '{print bc,$1,$3}' | sort | uniq -c | \
    gzip > mapped/trnCounts_LAST_${bc}_vs_Mmus_transcriptome.txt.gz;
done
```

Note: I've split this up into two steps (compared to previous versions of this protocol) so that an intermediate count of the total number of mapped transcripts per barcode can be done:

```
for bc in $(awk '{print $2}' barcode_counts.txt);
  do echo -n "${bc} ";
  zcat mapped/trnMapping_LAST_${bc}_vs_Mmus_transcriptome.txt.gz | \
   awk '{print $2}' | sort | uniq | wc -l;
```

Annotation and Result generation

5 count_analysis.r

Transcript counts are merged with ensembl gene annotation, then converted into wide format (one line per transcript) using an R script.

The transcript annotation in this case is from ensembl BioMart (see Guidelines for more details).

```
#!/usr/bin/env Rscript
library(dplyr);
library(tidyr);
## load ensemble transcript metadata (including gene name)
ensembl.df <- as.tbl(read.delim('ensembl mm10 geneFeatureLocations.txt.gz',</pre>
  col.names=c('transcript', 'Description', 'Start', 'End',
               'Strand', 'Gene', 'Chr'),
  stringsAsFactors=FALSE));
ensembl.df$Description <- sub(' \\[.*$','',ensembl.df$Description);</pre>
ensembl.df$Description <- sub('^(.{50}).+$','\\1...',ensembl.df$Description);</pre>
ensembl.df[,1:7] <- ensembl.df[,c(1,7,5,3,4,2,6)];
colnames(ensembl.df)[1:7] \leftarrow colnames(ensembl.df)[c(1,7,5,3,4,2,6)];
options(scipen=15); ## don't show scientific notation for large positions
## load used barcode identifiers
bcNames <- read.table("barcode counts.txt", stringsAsFactors=FALSE)[,2];</pre>
## load count data into 'narrow' array (one line per count)
trn.counts <- tibble(); for(bc in bcNames){</pre>
  trn.counts <-
    bind rows(trn.counts,
      as.tbl(read.table(
        sprintf('mapped/trnCounts LAST %s vs Mmus transcriptome.txt.gz', bc),
        col.names=c('count','barcode','transcript','dir'),
        stringsAsFactors=FALSE)));
}
## remove revision number from transcript names (if present)
trn.counts$transcript <- sub('\\.[0-9]+$','',trn.counts$transcript);</pre>
## convert to wide format (one line per transcript)
trn.counts.wide <- spread(trn.counts, barcode, count) %>%
  mutate(dir = c('+'='fwd', '-'='rev')[dir]);
for(bd in colnames(trn.counts.wide[,-1])){
  trn.counts.wide[[bd]] <- replace na(trn.counts.wide[[bd]],0);</pre>
}
## merge ensembl metadata with transcript counts
gene.counts.wide <- inner join(ensembl.df, trn.counts.wide, by='transcript');</pre>
qene.counts.wide <- gene.counts.wide[order(-rowSums(gene.counts.wide[,-(1:8)])),];</pre>
## write result out to a file
write.csv(gene.counts.wide, file='wide transcript counts LAST.csv',
  row.names=FALSE);
```

Downstream Workflows

A downstream workflow is still <u>in development</u>. I have had reasonable succes doing transcript-level differential expression analysis using <u>DESeq2</u>.

I would like to emphasise that batch effects should be considered for nanopore sequencing, given how frequently the technology changes. Make sure that at least the sequencing *library* (i.e. samples prepared in tandem on the same day from the same kit) is added into the statistical model, and try to make sure that sequencing libraries are fairly heterogeneous - replicates from a sample with skewed transcript distributions could influence the outcome of statistical tests.
